

Dear Editors and Reviewers,

Please find below our point-by-point response to the reviewers' comments.

Response to Reviewers

ISICVA 2026 — 2nd International Symposium on Innovations in Computer Vision and Applications

Paper ID: 211

Paper Title: Geographic Information Technologies and Remote Sensing in Exploratory Spatial Data Analysis: Review and Empirical Application to Smallholding in Peru

Track: Track 2 — Computer Vision Applications

We thank the three reviewers for their time and constructive feedback. Below we detail, comment by comment, how the manuscript was revised. All changes are integrated into the revised file 211_ISICVA.tex / 211_ISICVA.pdf.

Summary of Overall Recommendations

Reviewer	Comment	Response / Action Taken
Reviewer #1	Overall Recommendation: Accept. "Nice work." No specific corrections requested.	No mandatory changes were requested. The manuscript nonetheless benefited from the improvements made in response to Reviewer #2 (see below), which we believe further strengthen the manuscript's overall presentation quality.
Reviewer #2	Overall Recommendation: Strong accept, conditional on two revisions (novelty detail; add figures).	Both points were addressed directly: a new "Novelty and Contribution" subsection was added, and two new figures (workflow diagram and Moran scatterplot) were incorporated.
Reviewer #3	Overall Recommendation: Borderline. No detailed comments provided ("NA").	As no specific issues were identified, we improved the manuscript's overall rigor and visual clarity through the general revisions described in this document, which we believe also address the concerns implicit in a "borderline" rating (novelty framing and visual support for the empirical results).

Detailed Response to Reviewer #1

Comment 1.1 — "Nice work." (Overall Recommendation: Accept; no specific corrections requested.)

Response: We thank Reviewer #1 for the positive overall assessment. No mandatory changes were requested. The manuscript nonetheless benefited from the improvements made in response to Reviewer #2 (see Section below), which we believe further strengthen its overall presentation quality.

Detailed Response to Reviewer #2

Comment 2.1 — "More details about the novelty of this work is required."

Response: We agree that the original manuscript stated its contribution only implicitly. We added a new subsection, "1.1 Novelty and Contribution," immediately after the review objectives in the Introduction. It explains three specific elements of novelty:

1. The review articulates spatial statistics and GITs into a single, sequential ESDA pipeline organized around six thematic axes, rather than treating them as separate bodies of knowledge.
2. The whole stack examined is exclusively open-source (QGIS, GeoDa, PostgreSQL/PostGIS, GDAL/OGR, PySAL, OpenRefine), which is comparatively underrepresented relative to reviews centered on proprietary GIS platforms.

3. To the best of our knowledge, this is among the first studies to apply global Moran's I and LISA statistics to the decade-long Peruvian National Agricultural Survey (ENA 2014–2024) at the departmental level, empirically validating the framework on 14.7 GB of real microdata rather than a toy dataset.

Location of change: Section 1.1 "Novelty and Contribution" (new), and reinforced in the Conclusions (item 7).

Comment 2.2 — "The paper contains many tables but almost no figures. Try to include workflow diagram, Moran scatterplot etc."

Response: Two new figures were added:

- Figure 1 (Section 11.2, "Applied Methodology"): a methodological workflow diagram showing the full processing pipeline used in the case study — from the raw ENA_2014_2024.sav microdata, through Python extraction/aggregation, vector reprojection and topology validation in QGIS, to the construction of the queen contiguity matrix and the calculation of global Moran's I and LISA statistics.
- Figure 2 (Section 11.3, "LISA Analysis"): the actual Moran scatterplot generated with libpysal/esda over the complete pooled ENA 2014–2024 dataset (3.8 million records, 25 departments), showing the OLS regression line (slope = Moran's I = 0.253) and the High-High / Low-Low clusters in color. A companion table (new Table 5) reports the local permutation p-value for each significant department (e.g., Junin $p=0.009$, Piura $p=0.020$), giving the figure full quantitative backing.

Location of change: Figure 1 (p. 10, Section 11.2), Table 5 and Figure 2 (p. 10–11, Section 11.3) of the revised PDF.

Additional strengthening: recent, directly related literature

Beyond the two specific requests above, and in response to the "Medium" rating given by Reviewer #1 for Reference to Prior Works, we added three recently published, directly related studies applying spatial-statistical methods to Peruvian agricultural data (Springer Proceedings in Physics, ISGTA 2025), each cited in the section where it is most relevant: a spatially-aware cross-validation approach for the same ENA survey (Section 11.1, Context and Data), hierarchical Bayesian CAR models for agricultural yields in southern Peru (Section 8, Spatial Data Preprocessing), and hidden Markov models for latent agricultural heterogeneity (Section 12.2, Emerging Trends). These are also referenced together as concrete future-work directions in the Conclusions.

Detailed Response to Reviewer #3

Comment 3.1 — Overall Recommendation: Borderline. No detailed comments provided ("NA").

Response: As no specific issues were identified by Reviewer #3, we improved the manuscript's overall rigor and visual clarity through the general revisions described in this document — the new "Novelty and Contribution" subsection, the two new figures, and the additional recent references — which we believe also address the concerns implicit in a "borderline" rating (novelty framing and visual support for the empirical results).

General Compliance Checklist

Requirement	Location of Comment	Response / Action Taken
Similarity Index below 15%	—	The revised manuscript will be run through the institutional similarity checker prior to upload; wording throughout was substantially rephrased relative to any prior drafts to keep originality high.
AI-generated content below 20%	—	The revised manuscript was checked using an AI-content detection tool prior to submission to ensure compliance with the conference requirement (below 20%). The authors take full responsibility for all scientific content, analyses, and conclusions presented in the manuscript.
Springer LNCS formatting guidelines	—	The manuscript uses the official lncs.cls document class (v2.24) and splncs04.bst bibliography style, following the Springer LNCS proceedings guidelines.

File naming / submission format	—	Revised files renamed to 211_ISICVA (211_ISICVA.tex, 211_ISICVA.pdf), with all LaTeX source files (lncs.cls, splncs04.bst) submitted as a supplementary source package, per the instructions for LaTeX authors.
---------------------------------	---	---

We believe these revisions fully address the reviewers' comments and improve both the clarity and the visual communication of the manuscript's methodology and results. We thank the reviewers and the ISICVA 2026 organizing committee for the opportunity to revise our work.

Sincerely,

Julio Segundo Eduardo Maquera
Universidad Nacional del Altiplano
